ABSTRACT OF THE DISCLOSURE:

A flexible insulating duct has excellent noncombustibility and insulating characteristics as well as productivity, and is formed by an elongated spiral body having plural turns and is obtained by wrapping glass wool or some other insulating material with a noncombustible cloth or some other noncombustible sheet type material. When the spiral body is wound, a preceding turn thereof and a following turn thereof are bonded to each other so that the noncombustibility of a final product is not lost, or are joined to each other firmly via a noncombustible joint member.
